This talk focuses on finding the stories in the data

Design of effective displays is iterative

Complex displays start with simple conceptual sketches

Example 1

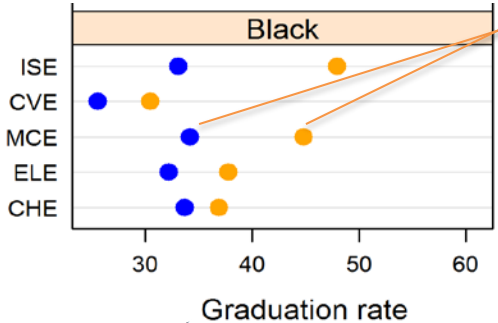

Iteratively exploring the starters' graduation rates

In an initial look at graduation rate, we placed men and women on the same row.

version 1

A multiway design facilitates comparisons within a panel.

Compare by **sex**
One **race**,
compare by **major**

A multiway design facilitates comparisons within a panel.

version 1

Order panels by median by race

Order rows by median by major

Compare by sex
One race,
compare by major

In the dual multiway, we swap the roles of rows and panels.

version 2

Order panels by median
by major

Compare by sex

Order rows by median
by race

One major,
compare by race

The next iteration placed men and women on separate rows

Rows are race + sex

We omit International and Other

In this design, the rows are ordered by the data in the panel

version 3

Order rows
by data
in panel

One major,
compare by race/sex

In this design, the rows are ordered by the data in the panel

version 3

Order panels by median in the panel

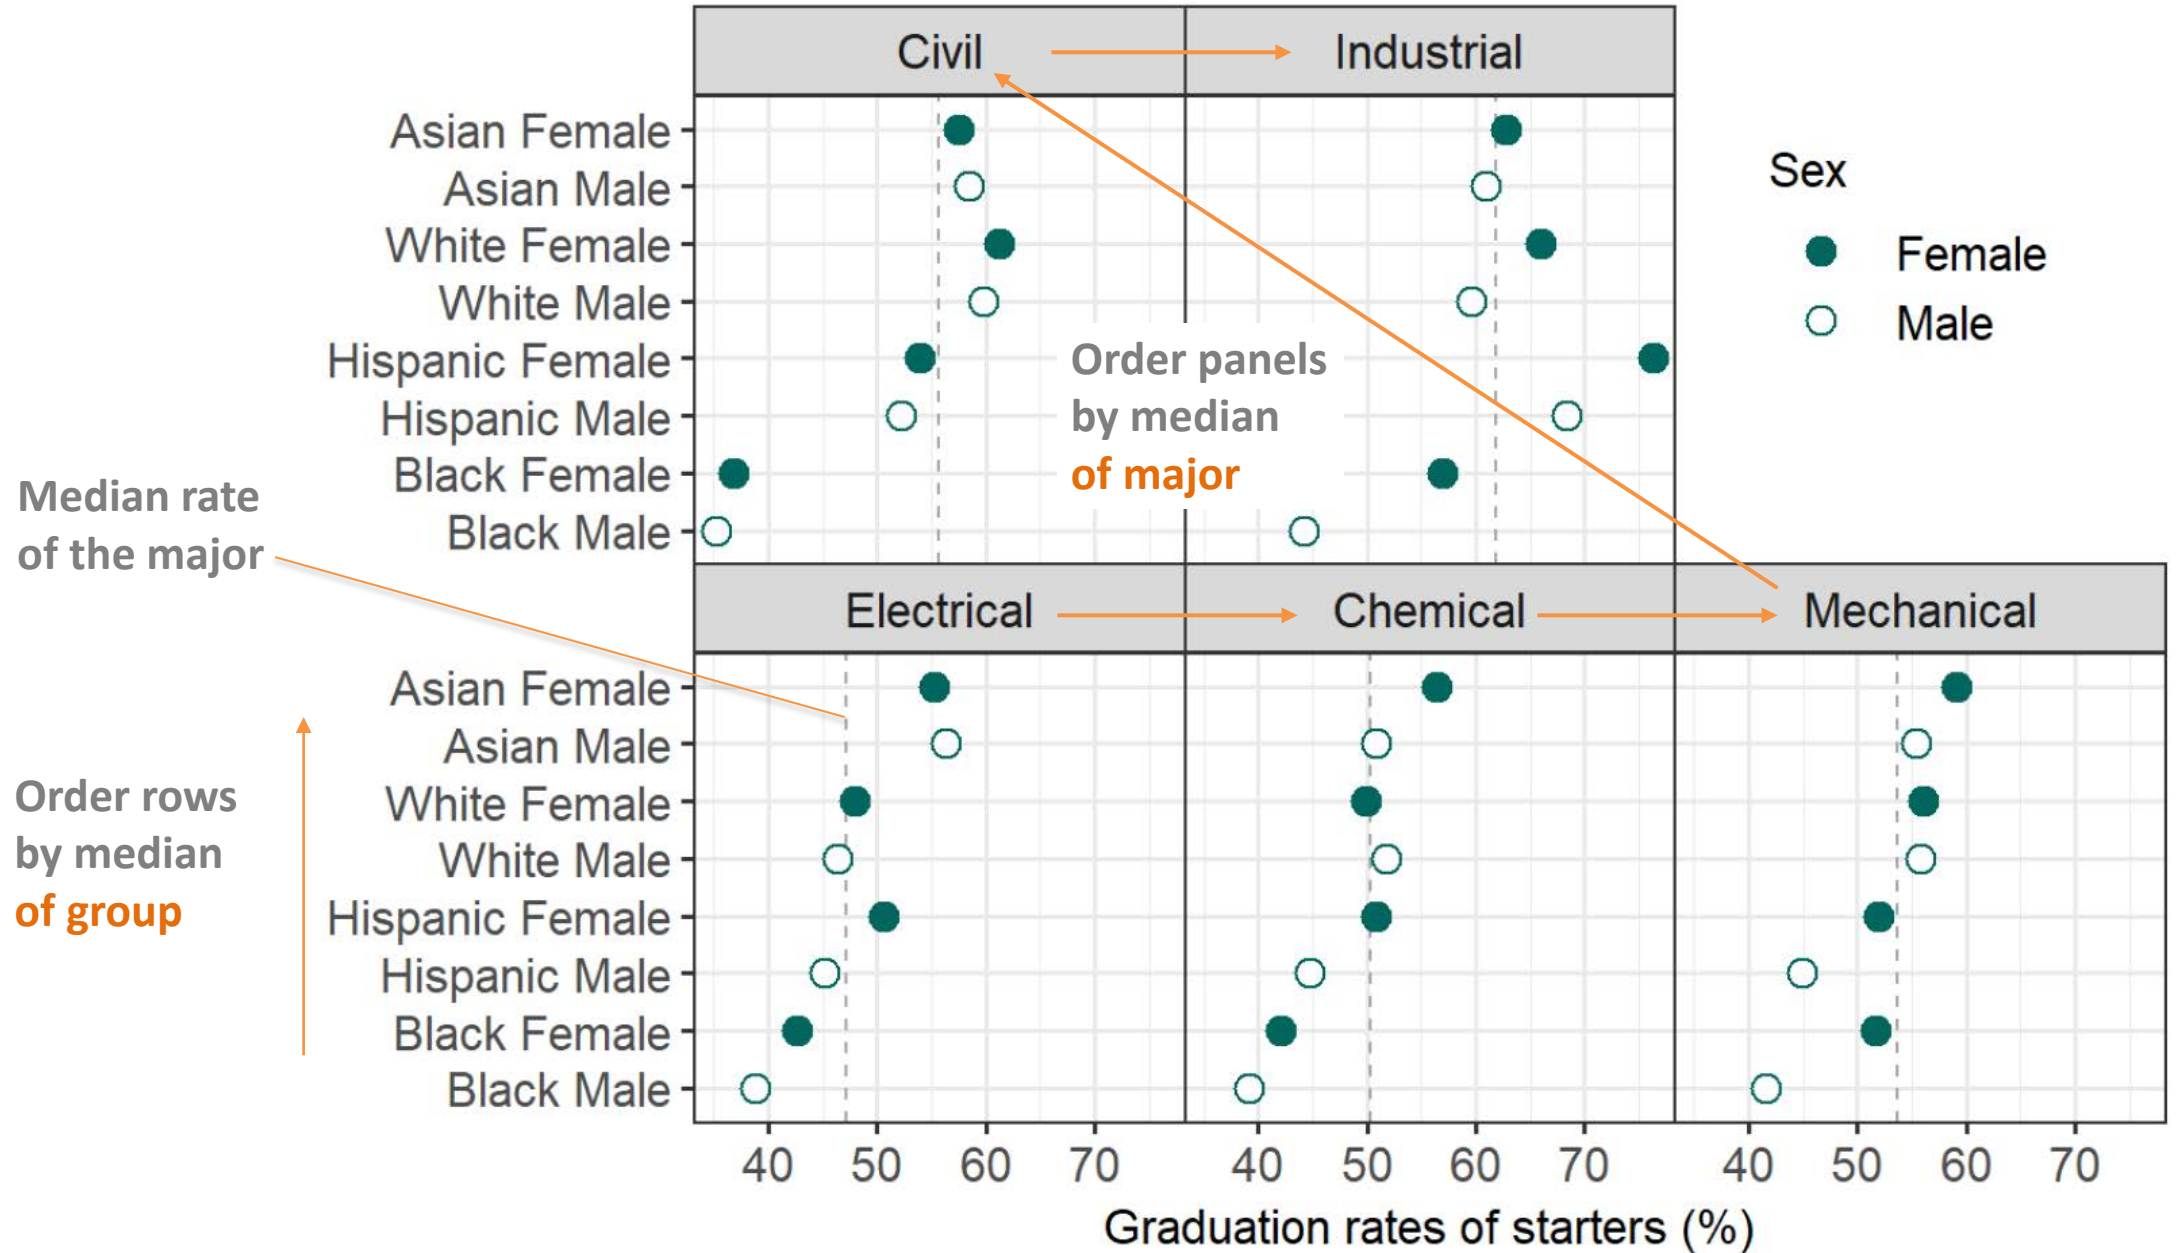

Order rows by data in panel

One major, compare by race/sex

In the final design, all rows are in the same order

version 4

This multiway design highlights visual anomalies.

version 4

This multiway design highlights visual anomalies.

version 4

Example 2

Iteratively exploring the migrators' stories

Initially we sketched and discussed around a white board.

In our first attempt we asked where grads in a major started

Same graph, 5 majors

The visual story didn't seem meaningful

version 1

We constructed a new metric

A new metric, **migration yield**,
was hinted at in our initial
brainstorming.

We constructed a new metric

Pool (839)

Black Male students in EE
839 potential migrators to EE

Of those, 386 migrated to EE
Fraction of migrators attracted = $386 / 839 = 0.460$

Migrate (386)

Of those, 184 graduated in EE
Fraction attracted that graduate = $184 / 386 = 0.477$

Graduate (184)

Migration yield is computed in one of two ways:
Product of the two fractions: $0.460 \times 0.477 = 22\%$
Ratio of graduates to pool: $184 / 839 = 22\%$

In the first attempt, we graphed migration yield directly

version 2

Same graph, 5 majors

version 2

Order rows
by the
data values

Clustered by sex

Clustered by race

Clustered by sex

We realized we had two distinct concepts contributing to migration yield

The fraction of the pool who were attracted

×

The fraction of those who graduated

= migration yield

Pool (839)

Migrate (386)

Graduate (184)

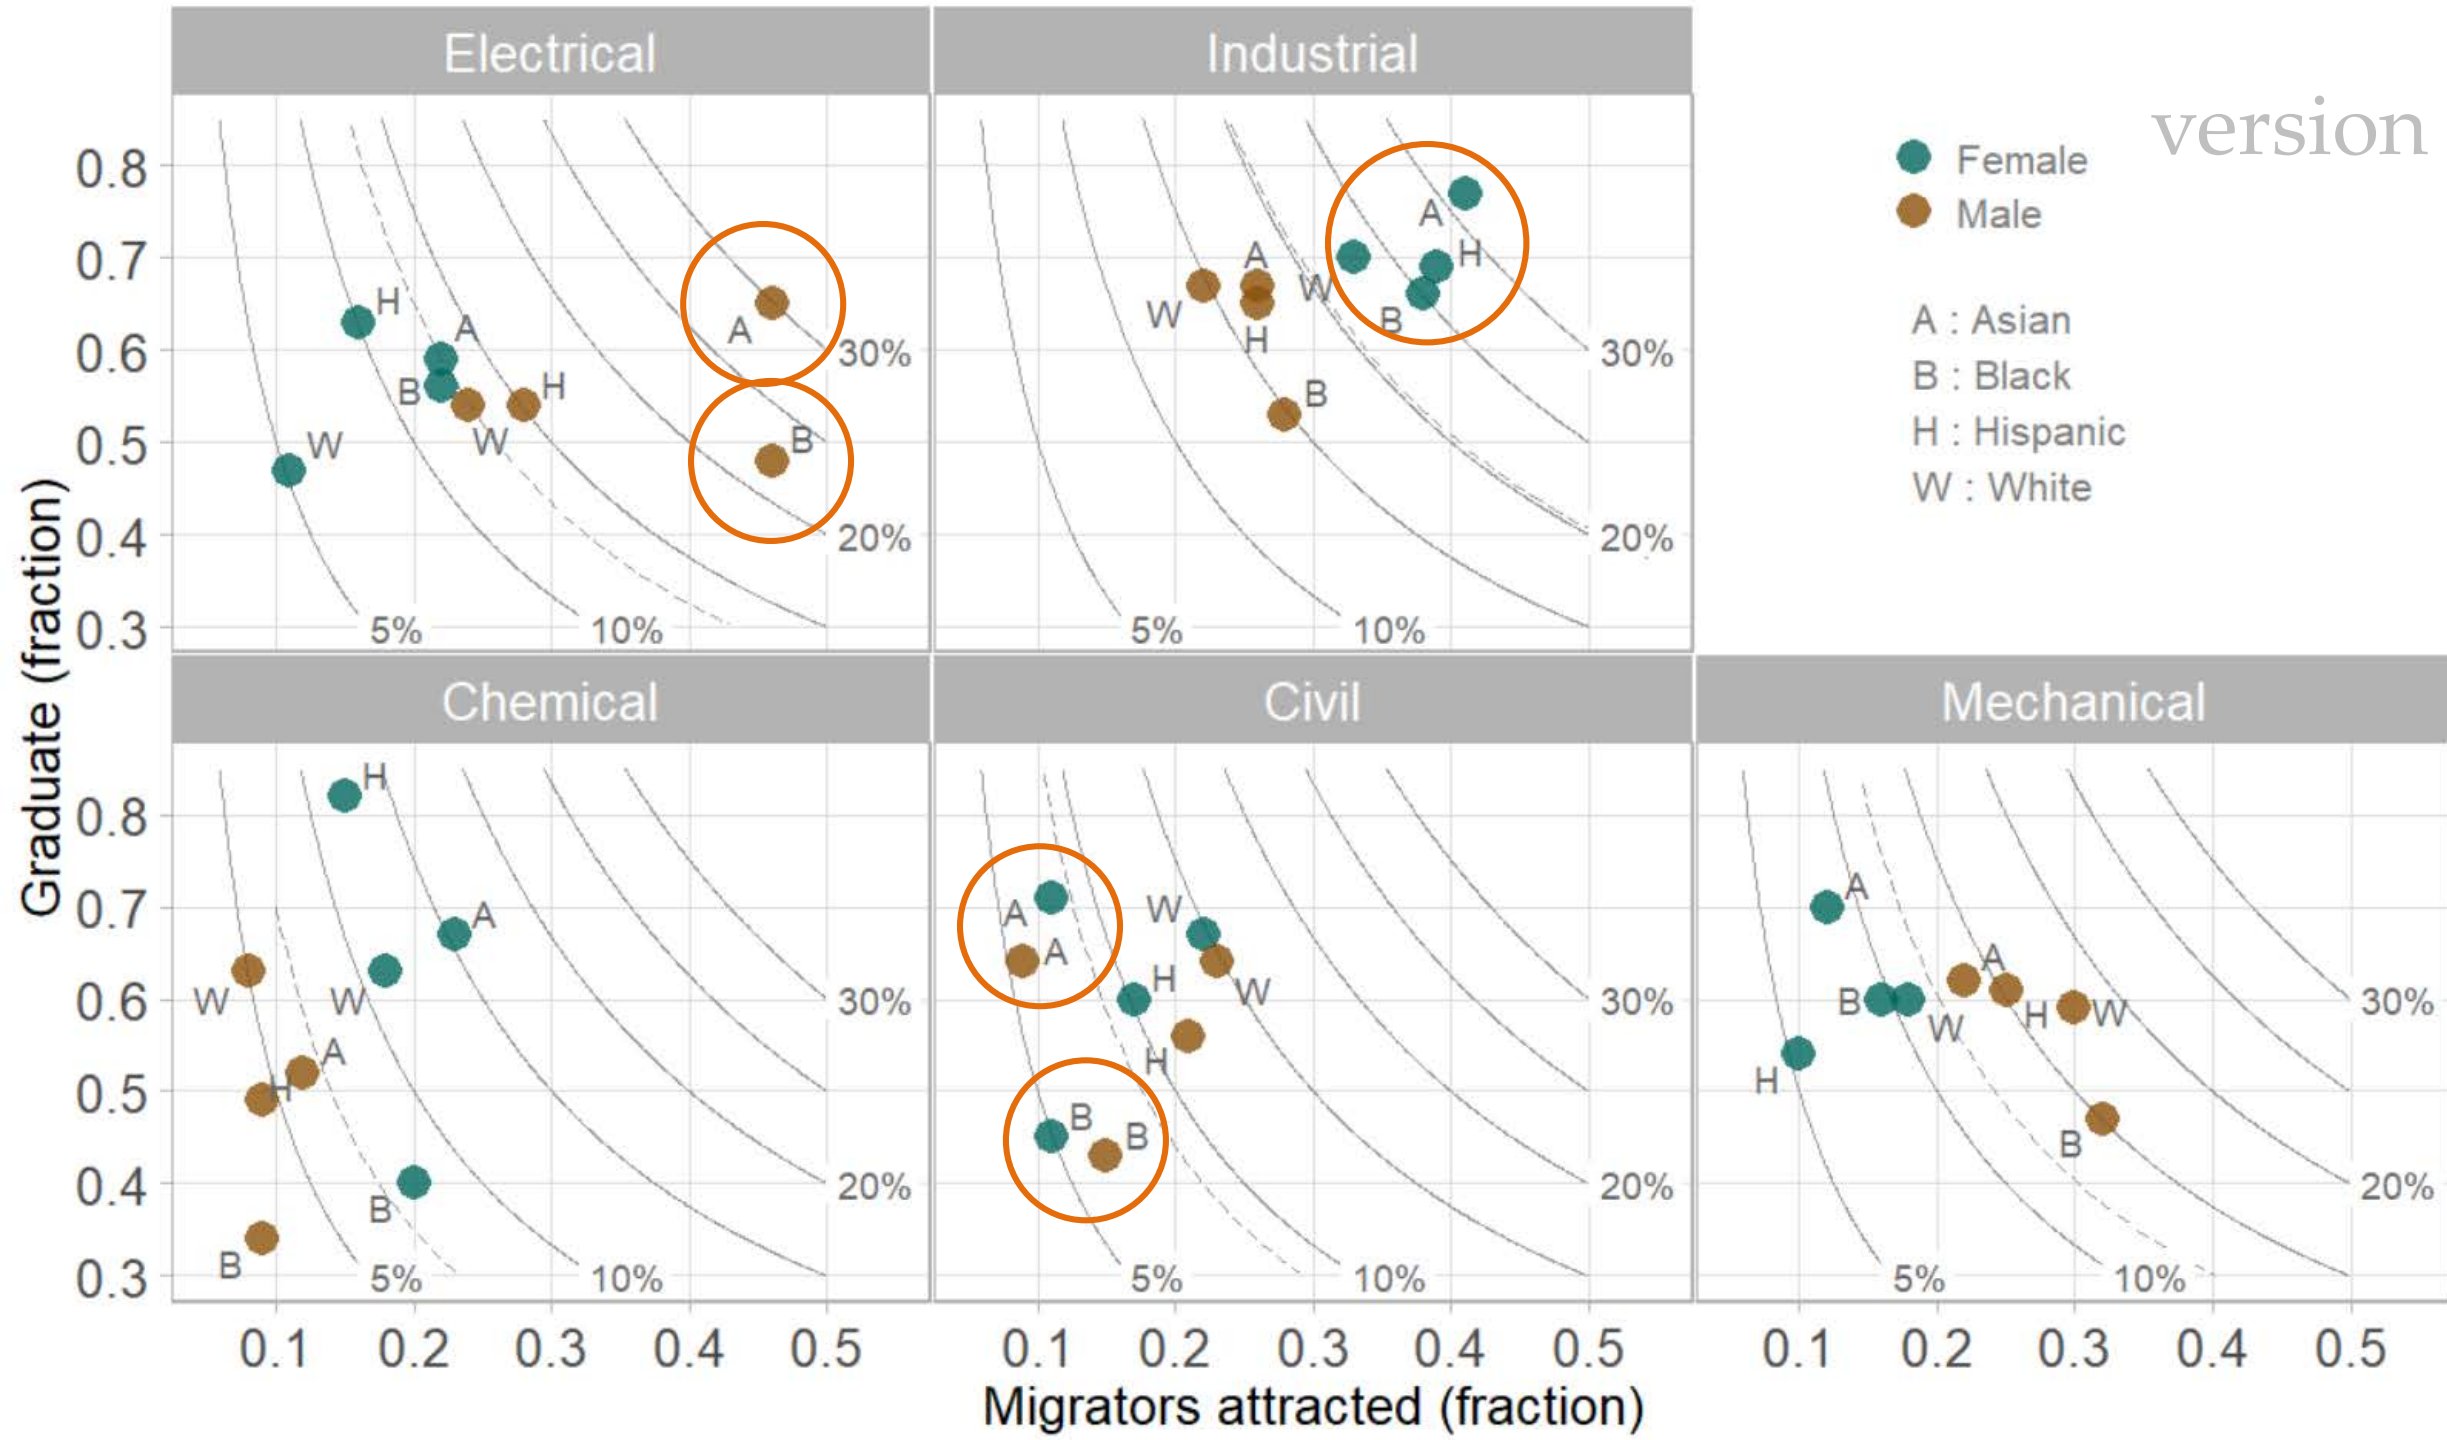

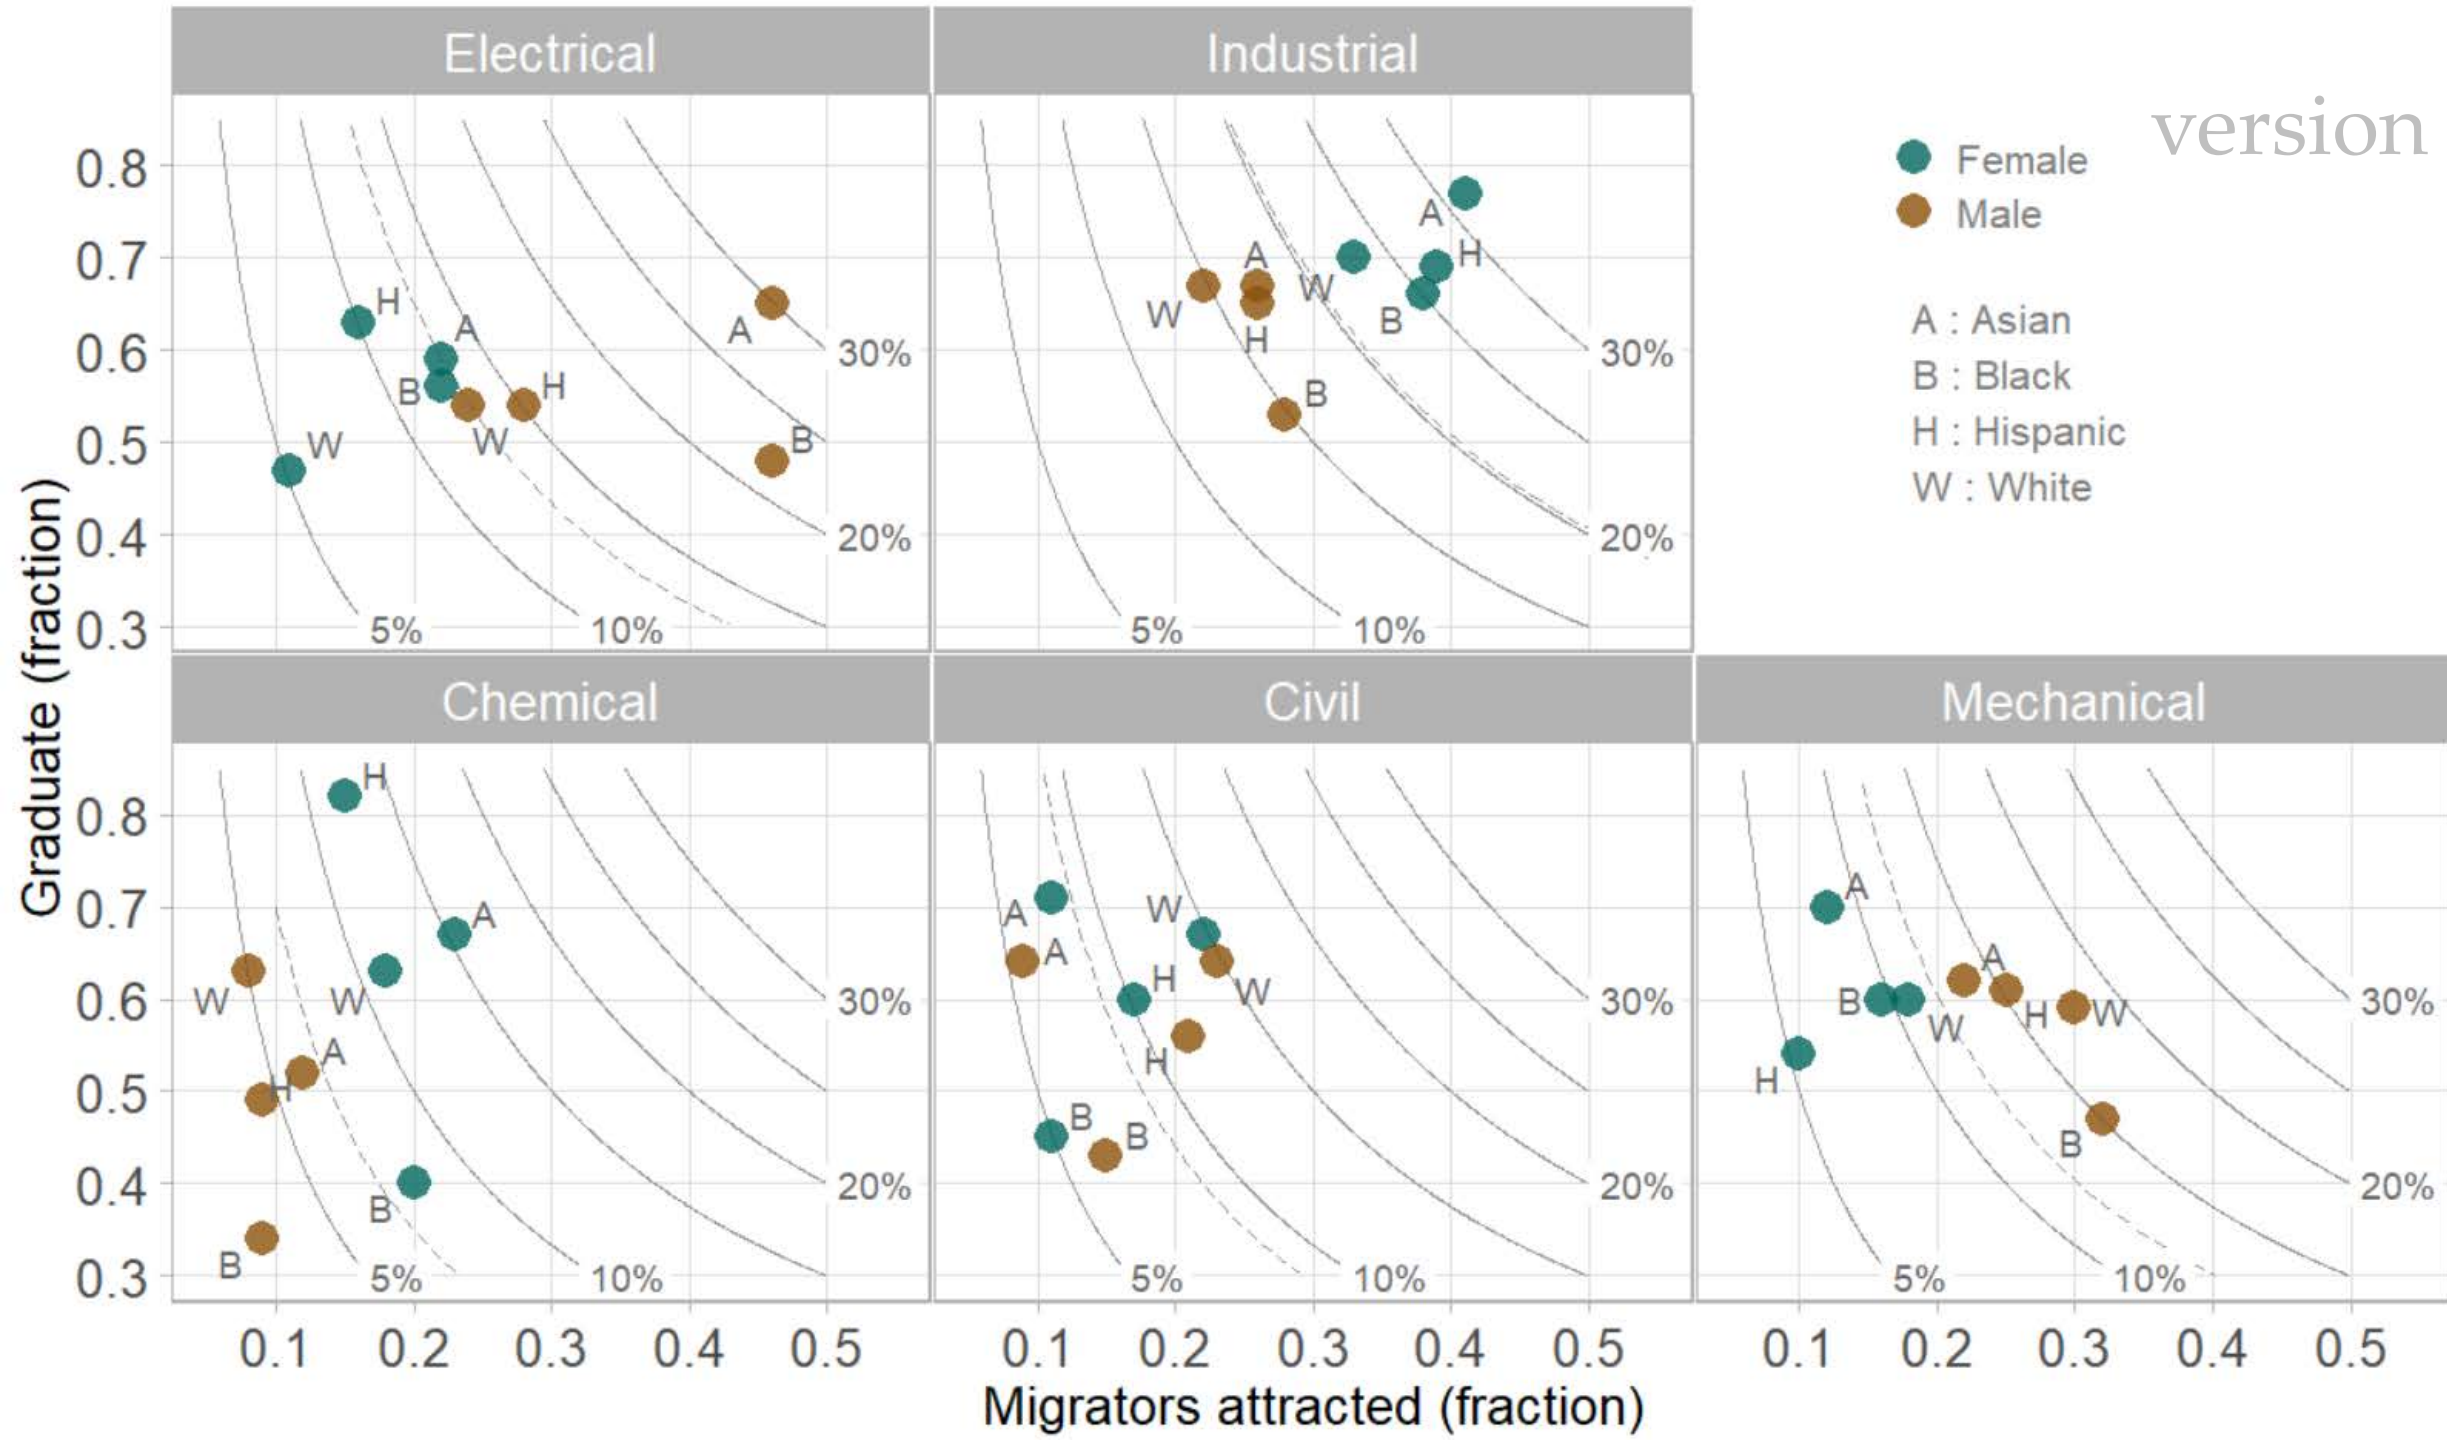

In a Cartesian graph, a constant product is a contour

version 3

In summary, effective design is both iterative and creative

Software proficiency is necessary
for effective iteration...

... guided by the intellectual effort
needed to **construct an argument**
